Abstract
A 24-year retrospective study of amputees was conducted at the Prosthetic and Orthotic Unit of the Kowloon Rehabilitation Centre, the first and largest rehabilitation centre in Hong Kong. A review was made of 1821 patients and a rising trend of amputee population was demonstrated probably related to the population growth. The ratio of lower limb to upper limb amputees was 1.83 to 1. The mean age of the amputees was 39 years. The commonest cause of upper limb amputation was trauma (89%) and of lower limb amputation was infection (35%). Vascular diseases were not as common in Chinese as in Caucasian communities. These patterns of amputee population indicate the demand for prosthetic service and provide guidelines for future development.

Introduction
The total care of an amputee should start before the amputation. There have been extensive studies on the rehabilitation of amputees. The medico-social aspect of the care should be based on accurate epidemiological data of the community, which will provide guidelines for the planning and implementation of the prosthetic service. Hughes (1983) has emphatically indicated the urgent requirement for a survey of the needs of the prosthetic service in Hong Kong. This survey has been conducted with the intention of serving future planning in the local prosthetic service.

Material and method
A retrospective study was carried out of all the records of the Prosthetic and Orthotic Unit at the Kowloon Rehabilitation Centre. The period of this study was 24 years, from January 1, 1960 to October 30, 1983. Each amputee was counted once at his/her first registration at the centre. The following data were collected and analysed:
- Total number of amputees
- Age
- Sex
- Cause of amputation
- Site and type of amputation

Five periods (one of 4 years and four of 5 years) were considered in the statistical analysis.

Results
(1) Number of amputees (Table 1)
There had been a steady increase in the total number of amputees over the first 18 years. The growth rate had been moderate (<20%) at the start until the “74-78” period when a remarkable 62% increase was recorded. Thereafter there was a sharp decline of 32% in the last 5 years.

(2) Age
The mean age of amputees was 39.05, but the distribution ranged from less than 1 year to 89 years of age. Female amputees had a higher mean age (44-74) than males (37-03).

An interesting feature of the mean age distribution (Table 2) was that there was a definite rising trend from 31.79 in the “60-63”

155
period to 44.02 in the “79–83” period. This trend was more remarkable among the female amputees who had a mean age of 53.20 in the “79–83” period, compared with only 31.75 in the “60–63” period.

When the ages were broken down into 4 specific groups (Table 3), it was evident that the largest number of amputees fell within the 21–40 age group (34.7%) while those between 41–60 formed the second majority group (29.3%). The distribution did, however, change over the period of the survey.

(3) Sex

Among the 1821 amputees, there was a strong male preponderance: 1363 male (74.9%), compared with 452 females (24.8%). The overall male to female ratio was 3:1 (ranging from 2.30:1 to 3.83:1 in different periods).

When the specific age groups were analysed with respect to sex distribution, there were several interesting features (Table 4). Among the younger amputees of 21–40, the male to female ratio was almost doubled to 6:1 compared to the overall pattern. On the other hand, there appeared to be a steady increase in the number of female amputees over the age of 61, so much so that among the oldest amputees of “79–83” period, there were more females than males.

(4) Site and type of amputation

There were 1,178 (65%) lower limb amputees and 641 (35%) upper limb amputees, the ratio being 1:83:1.

The types of amputation are shown in Table 5, the commonest being below-knee amputation (37%), followed by above-knee (16%), below-elbow (15%) and hand amputation (13%).

The age distribution of 543 of the upper limb amputees was analysed (Table 6) and 248 patients (45.7%) were found to fall within the 21–40 age group. The commonest varieties were hand amputations and below-elbow amputations.

The age distribution of 923 lower limb amputees was analysed (Table 7) and a different picture was revealed. The commonest age group was 41–60 (32.1%), followed by >60 (28.5%) and then 21–40 (24.6%). Below-knee amputation was the commonest variety among the lower
When the causes of amputation were tabulated against the 4 different age groups, specific correlations were obvious (Table 10). 78% of congenital amputees were found among the <20 age group; 41% (131) of traumatic amputees were found among the 21–40 age group; 47% (89) of infective amputees were found among the 41–60 age group; 34% (14) of neoplasms in the 21–40 age group; and 60% (104) of vascular and diabetic causes in the over 60 age group.

Discussion

The Prosthetic and Orthotic Unit in the Kowloon Rehabilitation Centre, Hong Kong, was the first established and the largest of the local limb fitting centres. This 24 year survey demonstrated the need for the development of prosthetic facilities. The steady rise in numbers of amputees in the successive periods identified was explained by the equivalent population growth (Hong Kong Census and Statistical Department 1976). A sharp increase in the “74–78” period was probably related to rapid growth and industrialization (Hong Kong Commission for Labour Department, 1976). The subsequent decline in the next period “78–83” was related to the diversion of a significant proportion of the amputee population to a new regional prosthetic and orthotic centre which was developed as part of the regionalization programme in the medical services in Hong Kong.

It is envisaged that there will be significant differences between the population structures in different regions. The present study should therefore be extended to other regional prosthetic and orthotic centres in order to get a panoramic view of the real need for prosthetic services. It is only through comprehensive surveys that reliable statistics may be obtained and hence prospective planning on the provision
of facilities and man-power be made meaningful.

The overall ratio of lower limb to upper limb amputees is 1.83:1. Among the upper limb amputees, trauma is the single commonest cause (89%) (Table 9). A medico-social study of occupational hand injuries in Hong Kong (Leung and Chan, 1981) indicated that the majority of these injuries were related to occupational hazards. It is therefore not surprising to find in this study that the majority of upper limb amputees are relatively young, 73% of them have ages of below 40, representing the major working force in industry (Table 6). The same reasons might explain the male and right-handed predominance (Table 8).

Among the lower limb amputees, there is a spread of pathological causes and age groups. Infection is the commonest group (35%), followed by vascular disease and diabetes mellitus (31%) and trauma (26%). There is also a relatively even distribution in age groups, 32% for those in the 41–60 group, 28% for the >60 and 25% for those in the 21–40 group (Table 7). In the early 60’s, leprosy was not uncommon in Hong Kong. This might account for a relatively high incidence of infection as a cause of amputation among the lower limb amputees. The problem of diabetes and peripheral vascular disease among the Chinese population seems to be less overwhelming than in most Caucasian communities, which commonly report a 60–70% incidence of vascular disease among lower limb amputees. In the same reports, a greater proportion of lower limb amputees are above 60 years of age (50% to 60%) Kerstein et al, 1975). In the last 5 years in Hong Kong, there has been an observable increase in the number of elderly lower limb amputees, particularly among the females (Table 2). If this pattern continues in the next decade or so, the pattern of amputation among the local Chinese population may resemble more closely that of the Western communities.

Whether this is due to changing life styles of the local population or other reasons may be revealed by further studies. Whatever the cause, the demand for prosthetic service is expected to follow closely the rising incidence of amputation.
